

# Securing Security Tools

## SuriCon 2016

Pierre Chifflier

[pierre.chifflier@ssi.gouv.fr](mailto:pierre.chifflier@ssi.gouv.fr)

French National Information Security Agency

2016

- ▶ Created on July 7th 2009, the ANSSI (French Network and Information Security Agency) is the national authority for the defense and the security of information systems.
- ▶ Under the authority of the Prime Minister
- ▶ Main missions are:
  - ▶ prevention
  - ▶ defense of information systems
  - ▶ awareness-rising

<http://www.ssi.gouv.fr/en/>

Objectives of this talk:

- ▶ Improving security of tools
- ▶ Not on small steps, but trying to solve problems
- ▶ Consider alternatives to common solutions
- ▶ Test our claims

## What is a network IDS ?

---

A device that

- ▶ monitors network for malicious activity
- ▶ does stateful protocol analysis
- ▶ raises alerts to the administrators
- ▶ has to be fast

## What is a network IDS ?

---

From the security point of view, a NIDS is:

- ▶ exposed to malicious traffic
- ▶ running lots of protocols dissectors
- ▶ connected to the admin network
- ▶ coded for performance

## Root causes

---

- ▶ Bad specifications
  - ▶ when they exist
- ▶ Design complexity and attack surface
- ▶ Formats complexity
- ▶ Programming language
- ▶ Paradox: many security tools are not securely coded
  - ▶ "I'll fix it later"
  - ▶ Infosec people considering it's "not their job"

## Miminal solutions

---

- ▶ Finding vulns does not (really) help security!
  - ▶ But it helps (raising awareness, demonstrating the problem, etc.)
  - ▶ The bug is fixed
  - ▶ But what about the (probably many) others?
- ▶ Fuzzing is not the solution either
  - ▶ Level o of security audit
  - ▶ But it works
- ▶ Building secure tools provides much more value
  - ▶ It's also much more complicated

## Solutions

---

- ▶ Software environment: minimize consequences of a problem
- ▶ Software: try to avoid problems

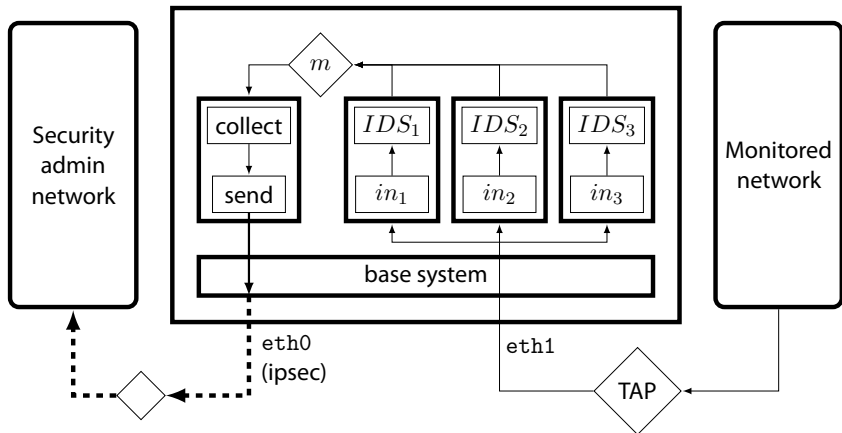

## Architecture Hardening: overview

---

- ▶ Reduced capabilities
- ▶ Isolated components
- ▶ Write  $\oplus$  Execute
- ▶ Send-only mechanism for logs
  - ▶ Tip: you can write data to a Unix socket in a RO-mounted partition
- ▶ Harden kernel
- ▶ Read-only containers (everything except `/run`)
- ▶ See [CF14] (french)

## Architecture

## Hardening software

---

- ▶ Reduce attack surface
- ▶ Secure design: simple, isolated components
- ▶ Managed memory

### Note on Suricata

- ▶ Good points:
  - ▶ Security awareness
  - ▶ Coding style
  - ▶ QA tools: unit tests, build bot, etc.
- ▶ But can we get rid of potential memory problems ?
  - ▶ Buffer overflows
  - ▶ Pointer arithmetic
  - ▶ Use-after-free
  - ▶ ...

Design changes:

- ▶ Split components
- ▶ Use adequate language
  
- ▶ Easy to say
- ▶ Let's try!

## The Rusticata proof of concept

---

### Motivations

- ▶ Isolate critical code (parsing)
  - ▶ Parsers should focus on protocols, not pointers
- ▶ Keep performance
- ▶ Build robust tools by design

## Why not C?

---

How to code a secure parser in C:

- a. defensive programming → fail
- b. use QA tools: unit tests, etc. → fail
- c. use fuzzing → fail
- d. you're the C god! → doubtful

Results: not so good

- ▶ Parsing is hard (ex: JSON [Ser16])
- ▶ For ex: Wireshark, 60 vulns in 2105, 57 in 2016
- ▶ Of course, my own code

## Alternatives

---

- ▶ OCaml, Haskell
- ▶ Python, Ruby, Perl
- ▶ Go, Rust
- ▶ C++, Java
- ▶ Lua
- ▶ Javascript

See [JO14] for why to exclude many of them

Yet another language? We want the following properties:

- ▶ Easy to embed
- ▶ Memory safety
- ▶ Strong typing<sup>1</sup>
- ▶ Thread safety
- ▶ No garbage collector (world stop)
- ▶ Fast data exchange with C
- ▶ Efficient, avoid useless copies
- ▶ Good community

Good candidate: Rust

---

<sup>1</sup>Which has nothing to do with pressing the keys harder

## Overview

---

Rusticata: 3 main parts

- ▶ Suricata: fake app-layer (C)
- ▶ Rusticata: glue layer, wraps the C arguments for Rust (Rust)
- ▶ Rust parsers: independant projects (Rust)

Notes

- ▶ Existing signature engine is used
- ▶ Log helper functions too

Nom [G.15] allows to describe data, and generate the parser

Reading bytes:

```
b1 = read_next_byte(&i);
type = b1 as u;
b2 = read_next_byte(&i);
b3 = read_next_byte(&i);
length = b2 >> 8 + b3; // big-endian
```

Describing data:

```
parse_record(&i) {
    type:    be_u8,
    length:  be_u16,
}
```

Better readability  $\Rightarrow$  less bugs

## Example: the SSL/TLS parser

---

- ▶ Secure almost all internet communications
- ▶ Complex protocol [BBDL<sup>+</sup>15]
- ▶ State-oriented parsing
- ▶ Multiple layers, application-level fragmentation
- ▶ Good comparison with the existing parser<sup>2</sup>

---

<sup>2</sup>I plead guilty for writing the previous one ...

## Example of changes (real code)

```
uint16_t cipher_suites_length =
    input[0] << 8 | input[1];
input += 2;

input += cipher_suites_length;

if (!(HAS_SPACE(1)))
    goto invalid_length;

/* skip compression methods */
uint8_t compression_methods_length =
    *(input++);

input += compression_methods_length;
```

```
ciphers_len: be_u16 ~
ciphers: flat_map!(take!(ciphers_len), parse_cipher_suites) ~
comp_len: take!(1) ~
comp: count!(be_u8, comp_len[0] as usize) ~
```

## The TLS parser

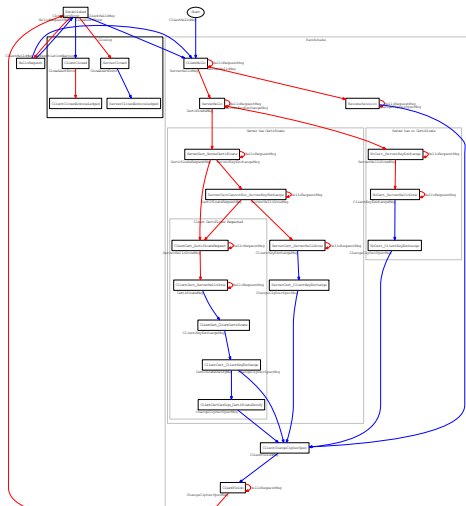

---

Skipping to the results (tech. details in other slides)

- ▶ covers SSLv3 to TLS 1.2
- ▶ more features than the C parser (extensions, defragmentation)
- ▶ some parts missing (detection keywords)
- ▶ less code: ~400 lines vs 800 for the same features
- ▶ rust parser is now ~900 lines
- ▶ less time to code
- ▶ almost entirely zero-copy
- ▶ **no unsafe code**

## Bonus: TLS state machine

- ▶ New parser offers possibilities to go further
- ▶ We can now express more complex security checks
- ▶ Extension: represent the TLS state machine
- ▶ Detect invalid transitions

## Bonus: TLS state machine

---

Rust representation:

```
match (state,msg) {
  (TlsState::None,          &TlsMessageHandshake::ClientHello(ref msg)) => {
    match msg.session_id {
      Some(_) => Ok(TlsState::AskResumeSession),
      -       => Ok(TlsState::ClientHello)
    }
  },
  // Server certificate
  (TlsState::ClientHello, &ServerHello(_))          => Ok(TlsState::ServerHello),
  (TlsState::ServerHello, &Certificate(_))          => Ok(TlsState::Certificate),
  // Server certificate, no client certificate requested
  (TlsState::Certificate, &ServerKeyExchange(_)) => Ok(TlsState::ServerKeyExchange)
```

Match possible on either message type or content

## Are we safe now?

---

Is the problem solved for good?

- ▶ Buffer overflows, pointer errors, double frees -> no more!
- ▶ Programming logic / algorithmic errors -> still here
- ▶ Compiler errors -> can happen

## Lessons learned

---

- ▶ Choosing a good language helps
  - ▶ Strong typing is great
  - ▶ Exhaustive pattern matching
- ▶ Cost: learning a new language
  - ▶ Lifetimes can be hard (for good reasons)
- ▶ Development time: same as C on first parsers, faster after
- ▶ Debugging time: **greatly reduced, no debugger required!**
- ▶ **No more segfault**

## Get the code

---

- ▶ Project main address: <https://github.com/rusticata>
- ▶ Suricata fake app-layer + detection
- ▶ Rusticata: wraps parsers (only TLS for now)
- ▶ Design document in the [Rusticata wiki](#)
- ▶ Rust parsers:
  - ▶ TLS
  - ▶ DER
  - ▶ NTP
  - ▶ SNMP
  - ▶ soon: X.509, IKEv2, ...

## Conclusion

---

- ▶ Looking at things differently is important
- ▶ Try to fix bugs for good
- ▶ Memory-safe parsers are a huge security improvement
  - ▶ Proof of concept: success
  - ▶ Not meant to replace all existing parsers
  - ▶ Requires some work to go further
- ▶ No global rewrite required, only sensitive code
